Searching for Patterns | Set 1 (Naive Pattern Searching)

Given a text *txt[0..n-1]* and a pattern *pat[0..m-1]*, write a function *search(char pat[], char txt[])* that prints all occurrences of *pat[]* in *txt[]*. You may assume that *n* > *m*.

Examples:
1) Input:

```
txt[] =  "THIS IS A TEST TEXT"
pat[] = "TEST"
```

Output:

```
Pattern found at index 10
```

2) Input:

```
txt[] =  "AABAACAADAABAAABAA"
pat[] = "AABA"
```

Output:

```
Pattern found at index 0
Pattern found at index 9
Pattern found at index 13
```

Pattern searching is an important problem in computer science. When we do search for a string in notepad/word file or browser or database, pattern searching algorithms are used to show the search results.

Naive Pattern Searching:
Slide the pattern over text one by one and check for a match. If a match is found, then slides by 1 again to check for subsequent matches.

```
#include<stdio.h>
#include<string.h>
void search(char *pat, char *txt)
{
    int M = strlen(pat);
    int N = strlen(txt);

    /* A loop to slide pat[] one by one */
    for (int i = 0; i <= N - M; i++)
    {
        int j;

        /* For current index i, check for pattern match */
        for (j = 0; j < M; j++)
        {
            if (txt[i+j] != pat[j])
                break;
        }
        if (j == M)  // if pat[0...M-1] = txt[i, i+1, ...i+M-1]
        {
           printf("Pattern found at index %d \n", i);
        }
    }
}

/* Driver program to test above function */
int main()
{
   char *txt = "AABAACAADAABAAABAA";
   char *pat = "AABA";
   search(pat, txt);
   getchar();
   return 0;
}
```

What is the best case?
The best case occurs when the first character of the pattern is not present in text at all.

```
txt[]   = "AABCCAADDEE"
pat[] = "FAA"
```

The number of comparisons in best case is O(n).

What is the worst case ?

The worst case of Naive Pattern Searching occurs in following scenarios.

1) When all characters of the text and pattern are same.

```
txt[] = "AAAAAAAAAAAAAAAAAA"
pat[] = "AAAAA".
```

2) Worst case also occurs when only the last character is different.

```
txt[] = "AAAAAAAAAAAAAAAAAB"
pat[] = "AAAAB"
```

Number of comparisons in worst case is O(m*(n-m+1)). Although strings which have repeated characters are not likely to appear in English text, they may well occur in other applications (for example, in binary texts). The KMP matching algorithm improves the worst case to O(n). We will be covering KMP in the next post. Also, we will be writing more posts to cover all pattern searching algorithms and data structures.

Dynamite ➚ pappu • 6 months ago

In the first example, you are doing comparison of (n-m+1) substrings ir comparison continues for m characters in the pattern, hence it is the w the pattern was BBBBB instead of AAAAA, in that case you would have text in the very first comparison with the pattern, as compared to m co the first example is worst case

manshi • 10 months ago

The given code has a flaw:
Try to find the pattern "ch" in string "aaaaaaaach"

Output: pattern doesn't exist

Correction:

```
/* instead of N-M, allow the loop till end of string */
for (int i = 0; i <= N ; i++)
{
int j;

/* For current index i, check for pattern match */
for (j = 0; j < M; j++)
{
if (txt[i+j] != pat[j])
break;
}
if (j == M) // if pat[0...M-1] = txt[i, i+1, ...i+M-1]
{
printf("Pattern found at index %d \n", i);
}
```

it works k!!The original explained program works k with yr input!!

Shiwakant Bharti ➚ manshi • 9 months ago

My adaptation of the given code in Java actually works. Please check y
i = N, j= 1, txt[i+j] will actually lead to ArrayIndexOutOfBoundsExceptior
C/C++.

gautam • 11 months ago

[sourcecode language="JAVA"]

```
public HashSet<Integer> naivePatternSearch(String pattern, String string) {
HashSet<Integer> index = new HashSet<Integer>();
for (int j = 0; j < string.length(); j++) {
for (int i = 0; i < pattern.length(); i++) {
if (pattern.charAt(i) == string.charAt(j+i)) {
if(i==pattern.length()-1){
index.add(j);
}
} else {
break;
}
}
}
return index;
```

A similar Approach through Recursion:

```
#include <stdio.h>
#include <string.h>
```

open in browser PRO version Are you a developer? Try out the HTML to PDF API pdfcrowd.com

```
int my_cmp(char* a,char* b,int i,int n);

int my_cmp(char* a,char* b,int i,int n)
{
                if(*(a+i)==*(b+(strlen(b)-n)))
                {
                        //printf("\nChecking i = %d ",i);
                        //printf("\nNow n = %d ",n);
                if(n==1)
                return 1;
                my_cmp(a,b,++i,--n);
                }
```

1 more approach could be as below:

```
bool isSubstring(char* src, char* pattern) {
int i=0,j=0, flag=0;
int lenp, lens;
for(i=0;*src+!='';i++);
lens = --i;
for(i=0;*pattern+i!='';i++);
lenp = --i;
i=0;

while((*(src+i)) ! = '')
{
```

open in browser PRO version Are you a developer? Try out the HTML to PDF API pdfcrowd.com

```
{
j++;
flag++;
if( flag == lenp)
```

The above algo is very similar to previous "Naive Pattern Search" algo but as t previous one uses 'for' loop, so novice programmers might have to spend few same algo as previous EXCEPT FEW LINES.

So I have written the above algo again using 'for' loop which is same as previo Search" algo) except two lines (added comment on those two lines) so that it's between two.

```
private void printPatternIndices(char[] text, char[] pattern) {

                for (int i = 0; i < text.length - pattern.length + 1;

                        int j;
                        for (j = 0; j < pattern.length; j++) {
                                if (text[i + j] != pattern[j]) {
                                        break;
                                }
```
