

## Detect if two integers have opposite signs

Given two signed integers, write a function that returns true if the signs of given integers are different, otherwise false. For example, the function should return true -1 and +100, and should return false for -100 and -200. The function should not use any of the arithmetic operators.

Let the given integers be x and y. The sign bit is 1 in negative numbers, and 0 in positive numbers. The XOR of x and y will have the sign bit as 1 iff they have opposite sign. In other words, XOR of x and y will be negative number number iff x and y have opposite signs. The following code use this logic.

```
#include<stdbool.h>
#include<stdio.h>

bool oppositeSigns(int x, int y)
{
    return ((x ^ y) < 0);
}

int main()
{
    int x = 100, y = -100;
    if (oppositeSigns(x, y) == true)
        printf ("Signs are opposite");
    else
        printf ("Signs are not opposite");
    return 0;
}
```

Output:

Signs are opposite

Source: [Detect if two integers have opposite signs](#)

We can also solve this by using two comparison operators. See the following code.

```
bool oppositeSigns(int x, int y)
{
    return (x < 0)? (y >= 0): (y < 0);
}
```

The first method is more efficient. The first method uses a bitwise XOR and a comparison operator. The second method uses two comparison operators and a bitwise XOR operation is more efficient compared to a comparison operation.

We can also use following method. It doesn't use any comparison operator. The method is suggested by Hongliang and improved by gaurav.

```
bool oppositeSigns(int x, int y)
{
    return ((x ^ y) >> 31);
}
```

The function is written only for compilers where size of an integer is 32 bit. The expression basically checks sign of  $(x \wedge y)$  using bitwise operator '>>'. As mentioned above, the sign bit for negative numbers is always 1. The sign bit is the leftmost bit in binary representation. So we need to check whether the 32th bit (or leftmost bit) of  $x \wedge y$  is 1 or not. We do it by right shifting the value of  $x \wedge y$  by 31, so that the sign bit becomes the least significant bit. If sign bit is 1, then the value of  $(x \wedge y) \gg 31$  will be 1, otherwise 0.

Please write comments if you find any of the above codes/algorithms incorrect, or find other ways to solve the same problem.

// can be done by these ways too..

```
unsigned int oppositeSign(unsigned int x,unsigned int y)
{
return !(x&y>>31)
```

//or

```
return (y&1(<<31))^(x&(1<<31))
}
```

In the last line of the last paragraph, it says:

"If sign bit is 1, then the value of  $(x \wedge y) \gg 31$  will be 1, otherwise 0"

But, if sign extension takes place, wherein the leftmost bits will be filled with 1 i value will be -1 and not 1.

So, I think it is better to say that, if the sign bit is 1, then the value of  $(x \wedge y) \gg 31$

why u people simply multiply them.  
int of opposite sign when multiple alwyz produce -ve value.  
why to complex simple logic.

```
if ( x * y < 0 )  
    return true // means they are opposite signs  
return false // they are of same sign
```

^ | v • Reply • Share ›

**dexterltd** → dexterltd • 2 years ago

sorry didn't read the question completely.  
missed the part "not to use the airthmetic operator.

^ | v • Reply • Share ›

**dexterltd** → dexterltd • 2 years ago

I meant why don't you simply multiply . Sorry for the Typo.

@Ravi, The `1 << sizeof(int)` doesn't work on my computer atleast

it gives `sizeof(int)` as 4 and thus, you get 15 instead of 31 on subtr:

^ | v • Reply • Share ›

**Vignesh** → sudhanshu • 4 months ago

`sizeof()` operator returns the size in bytes. so you need to multi  
a violation of the prerequisite 'no arithmetic op' :)

**Hongliang** · 2 years ago

Nice solution, but it still uses ">" for comparison (you might know that compari  
numbers, here it is one without using comparisons:

```
bool opp = ((x ^ y) & >> 31)
```

P.S. actually the webpage for bit hack is worth reading, highly recommended.

^ | v · Reply · Share ›

**gaurav** → Hongliang · 2 years ago

I think what you are trying to say is

```
bool opp = (x ^ y) >> 31)
```

but this would not work as right shift is arithmetic shift in c. So, the res

$((x \oplus y) \& 1 \ll 31)$  would work as suggested by kartik.

**kartik** → Hongliang • 2 years ago

@Hongliang: Thanks for suggesting the optimization. I think, the  
Following is the complete code.

```
#include<stdbool.h>
#include<stdio.h>

bool oppositeSigns(int x, int y)
{
    return ((x ^ y) & 1 << 31);
}

int main()
{
    int x = 100, y = -1000;
    if (oppositeSigns(x, y) == true)
        printf ("Signs are opposite");
    else
        printf ("Signs are not opposite");
    return 0;
}
```

^ | v • Reply • Share ›

**Pravesh** → kartik • 2 years ago

Kartik, Can you please explain it in deep,

why return  $((x \wedge y) \& 1 \ll 31)$  ?

^ | v · Reply · Share ›

**kartik** → Pravesh · 2 years ago

@Pravesh: The program is written only for compilers w

Two numbers are negative if the value of their XOR is n
