

Comparison of Inheritance in C++ and Java

The purpose of inheritance is same in C++ and Java. Inheritance is used in both languages for reusing code and/or creating is-a relationship. There are following differences in the way both languages provide support for inheritance.

1) In Java, all classes inherit from the **Object class** directly or indirectly. Therefore, there is always a single inheritance tree of classes in Java, and **Object class** is root of the tree. In Java, if we create a class that doesn't inherit from any class then it automatically inherits from **Object class**. In C++, there is forest of classes; when we create a class that doesn't inherit from anything, we create a new tree in forest.

Following Java example shows that Test class automatically inherits from Object class.

```
class Test {
    // members of test
}
class Main {
    public static void main(String[] args) {
        Test t = new Test();
        System.out.println("t is instanceof Object: " + (t instanceof Object));
    }
}
```

Output:

```
t is instanceof Object: true
```

2) In Java, members of the grandparent class are not directly accessible. See [this G-Fact](#) for more details.

3) The meaning of protected member access specifier is somewhat different in Java. In Java, protected members of a class “A” are accessible in other class “B” of same package, even if B doesn’t inherit from A (they both have to be in the same package). For example, in the following program, protected members of A are accessible in B.

```
// filename B.java
class A {
    protected int x = 10, y = 20;
}

class B {
    public static void main(String args[]) {
        A a = new A();
        System.out.println(a.x + " " + a.y);
    }
}
```

4) Java uses *extends* keyword for inheritance. Unlike C++, Java doesn’t provide an inheritance specifier like public, protected or private. Therefore, we cannot change the protection level of members of base class in Java, if some data member is public or protected in base class then it remains public or protected in derived class. Like C++, private members of base class are not accessible in derived class.

Unlike C++, in Java, we don’t have to remember those rules of inheritance which are combination of base class access specifier and inheritance specifier.

5) In Java, methods are virtual by default. In C++, we explicitly use virtual keyword. See [this G-Fact](#) for more details.

6) Java uses a separate keyword *interface* for interfaces, and *abstract* keyword for abstract classes and abstract functions.

Following is a Java abstract class example.

```
// An abstract class example
abstract class myAbstractClass {

    // An abstract method
```

```

abstract void myAbstractFun();

// A normal method
void fun() {
    System.out.println("Inside My fun");
}

public class myClass extends myAbstractClass {
    public void myAbstractFun() {
        System.out.println("Inside My fun");
    }
}

```

Following is a Java interface example

```

// An interface example
public interface myInterface {
    // myAbstractFun() is public and abstract, even if we don't use the
    void myAbstractFun(); // is same as public abstract void myAbstractFun()
}

// Note the implements keyword also.
public class myClass implements myInterface {
    public void myAbstractFun() {
        System.out.println("Inside My fun");
    }
}

```

7) Unlike C++, Java doesn't support multiple inheritance. A class cannot inherit from more than one class. A class can implement multiple interfaces though.

8) In C++, default constructor of parent class is automatically called, but if we want to call parametrized constructor of a parent class, we must use **Initializer list**. Like C++, default constructor of the parent class is automatically called in Java, but if we want to call parametrized constructor then we must use **super** to call the parent constructor. See following Java example.

```

package main;

class Base {
    private int b;
    Base(int x) {

```

Deploy Early. Deploy Often.

Automation

FIND OUT HOW ►

```

        b = x;
        System.out.println("Base constructor called");
    }
}

class Derived extends Base {
    private int d;
    Derived(int x, int y) {
        // Calling parent class parameterized constructor
        // Call to parent constructor must be the first line in a Deri
        super(x);
        d = y;
        System.out.println("Derived constructor called");
    }
}

class Main{
    public static void main(String[] args) {
        Derived obj = new Derived(1, 2);
    }
}

```

Output:

```

Base constructor called
Derived constructor called

```

You can add one more point about the Garbage Collector facility in Java.

"Java doesn't provide an inheritance specifier like public, protected or private. " protection level of members of base class in Java, if some data member is pu remains public or protected in derived class".

I'm not sure if this is right. AFAIK we can't make the protection level restrictive. But something like Protected to Public is allowed.
