

Iterative Quick Sort

Following is a typical recursive implementation of **Quick Sort** that uses last element as pivot.

```
/* A typical recursive implementation of quick sort */

/* This function takes last element as pivot, places the pivot element
   correct position in sorted array, and places all smaller (smaller than
   to left of pivot and all greater elements to right of pivot */
int partition (int arr[], int l, int h)
{
    int x = arr[h];
    int i = (l - 1);

    for (int j = l; j <= h- 1; j++)
    {
        if (arr[j] <= x)
        {
            i++;
            swap (&arr[i], &arr[j]);
        }
    }
    swap (&arr[i + 1], &arr[h]);
    return (i + 1);
}

/* A[] --> Array to be sorted, l --> Starting index, h --> Ending index */
void quickSort(int A[], int l, int h)
{
    if (l < h)
    {
        int p = partition(A, l, h); /* Partitioning index */
        quickSort(A, l, p - 1);
        quickSort(A, p + 1, h);
    }
}
```

The above implementation can be optimized in many ways

1) The above implementation uses last index as pivot. This causes worst-case behavior on already sorted arrays, which is a commonly occurring case. The problem can be solved by choosing either a random index for the pivot, or choosing the middle index of the partition or choosing the median of the first, middle and last element of the partition for the pivot. (See [this](#) for details)

2) To reduce the recursion depth, recur first for the smaller half of the array, and use a tail call to recurse into the other.

3) Insertion sort works better for small subarrays. Insertion sort can be used for invocations on such small arrays (i.e. where the length is less than a threshold t determined experimentally). For example, [this](#) library implementation of qsort uses insertion sort below size 7.

Despite above optimizations, the function remains recursive and uses **function call stack** to store intermediate values of l and h . The function call stack stores other bookkeeping information together with parameters. Also, function calls involve overheads like storing activation record of the caller function and then resuming execution.

The above function can be easily converted to iterative version with the help of an auxiliary stack. Following is an iterative implementation of the above recursive code.

```
// An iterative implementation of quick sort
#include <stdio.h>

// A utility function to swap two elements
void swap ( int* a, int* b )
{
    int t = *a;
    *a = *b;
    *b = t;
}

/* This function is same in both iterative and recursive*/
int partition (int arr[], int l, int h)
{
    int x = arr[h];
    int i = (l - 1);
```

```

for (int j = l; j <= h- 1; j++)
{
    if (arr[j] <= x)
    {
        i++;
        swap (&arr[i], &arr[j]);
    }
}
swap (&arr[i + 1], &arr[h]);
return (i + 1);
}

/* A[] --> Array to be sorted, l --> Starting index, h --> Ending index
void quickSortIterative (int arr[], int l, int h)
{
    // Create an auxiliary stack
    int stack[ h - l + 1 ];

    // initialize top of stack
    int top = -1;

    // push initial values of l and h to stack
    stack[ ++top ] = l;
    stack[ ++top ] = h;

    // Keep popping from stack while is not empty
    while ( top >= 0 )
    {
        // Pop h and l
        h = stack[ top-- ];
        l = stack[ top-- ];

        // Set pivot element at its correct position in sorted array
        int p = partition( arr, l, h );

        // If there are elements on left side of pivot, then push left
        // side to stack
        if ( p-1 > l )
        {
            stack[ ++top ] = l;
            stack[ ++top ] = p - 1;
        }

        // If there are elements on right side of pivot, then push right
        // side to stack
        if ( p+1 < h )
        {

```

```

        stack[ ++top ] = p + 1;
        stack[ ++top ] = h;
    }
}

// A utility function to print contents of arr
void printArr( int arr[], int n )
{
    int i;
    for ( i = 0; i < n; ++i )
        printf( "%d ", arr[i] );
}

// Driver program to test above functions
int main()
{
    int arr[] = {4, 3, 5, 2, 1, 3, 2, 3};
    int n = sizeof( arr ) / sizeof( *arr );
    quickSortIterative( arr, 0, n - 1 );
    printArr( arr, n );
    return 0;
}

```

Output:

```
1 2 2 3 3 3 4 5
```

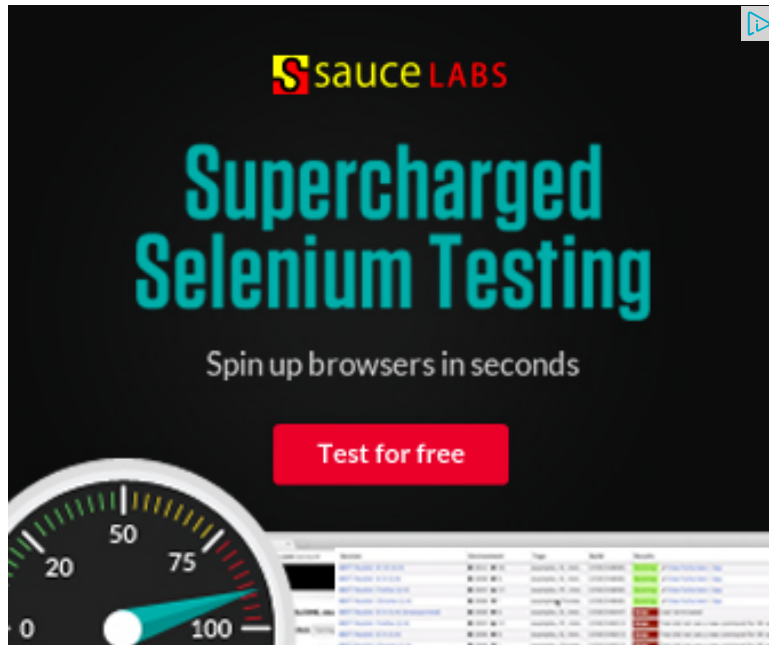

The above mentioned optimizations for recursive quick sort can also be applied to iterative version.

- 1) Partition process is same in both recursive and iterative. The same techniques to choose optimal pivot can also be applied to iterative version.
- 2) To reduce the stack size, first push the indexes of smaller half.
- 3) Use insertion sort when the size reduces below a experimentally calculated threshold.

1. To reduce the recursion depth, recur first for the smaller half of the array, and then for the other.

2. To reduce the stack size, first push the indexes of smaller half.

Please elaborate.

Thanks

^ | v ·

Quick Sort is a Sorting Algorithm based on Divide And Conquer Technique. I have also a good reference with Description, Program Example, Snapshot and a simple explanation

[http://geeksprogrammings.blogspot...](http://geeksprogrammings.blogspot.in/2014/05/quick-sort.html)

We can improve performance of partition function, by simply checking the `a[j]` swap function will call. eg,

```
int partition(int a[],int l,int h)
{
    int x=a[h];
    int i=l-1,j;
```

```
for(j=1;j<=h-1;++j)
{
    if(a[j]<x &&" a[j]!="a[++i]" {="" swap(&a[j],&a[i]
```

How will recursion depth be reduced if we recur smaller part of the array first?

1 ^ | v .

??? · a year ago

Not a kind explanation, but also terrific code I think! Thanks a lot!

^ | v .

Aashish Barnwal · a year ago

The boundaries high(h) and low(l) are not necessary to specify. However, the to pass as a parameter. So the method signature can be reduced to:
void quickSortIterative (int arr[], int size).

^ | v .

Kuldeep Tiwari · a year ago

With iterative implementation, we don't need parameters low(l) and high(h) in signature reduces to -
void quickSortIterative (int arr[]).

^ | v ·

kuldeep · a year ago

With iterative implementation, we don't need parameters low(l) and high(h) in signature reduces to -
void quickSortIterative (int arr[]).

Quick Sort with (Stable+ Efficient+ in-place Sorting+ NO Need of partition method including repeating elements) is given below (java):

```
public static void quickSort(int A[], int l, int h)
{
    int pivot=(l+h)/2;
    int pivotValue=A[pivot];

    int i=l, j=h;
    while(i<=j)
    {
        while(A[i]<pivotValue)
            i++;
        while(A[j]>pivotValue)
            j--;
        if(i<j)
            swap(A[i], A[j]);
    }
    quickSort(A, l, j);
    quickSort(A, j+1, h);
}
```

```
while(A[j]>pivotValue)
    j--;

if(i<=j)
```

sindhu → Anonymous · a year ago

Above code will run into infinite loop for input:
40 20 10 80 60 50 7 30 100 - take 60 as pivot element.

^ | v .

Anonymous → sindhu · a year ago

I have tried my code with above sample input---
40 20 10 80 60 50 7 30 100 - take 60 as pivot element. It is work

^ | v .

Rahul → Anonymous · a year ago

You are basically implementing the partition method inside quicksort. In this way are you improving quick sort. You are just writing the same code.

```
/* Paste your code here (You may delete these lines) */
```

^ | v .

Anonymous → Rahul · a year ago

@Rahul- Yes. I am implementing partition code inside quicksort. I have improved the efficiency. Efficiency can be improved by choosing a better pivot element correctly which can be done if we use a randomize function to choose the elements of input array and then applying quicksort.

input array.
