

## Divide and Conquer | Set 6 (Search in a Row-wise and Column-wise Sorted 2D Array)

Given an  $n \times n$  matrix, where every row and column is sorted in increasing order. Given a key, how to decide whether this key is in the matrix.

A linear time complexity is discussed in the previous post. This problem can also be a very good example for divide and conquer algorithms. Following is divide and conquer algorithm.

- 1) Find the middle element.
- 2) If middle element is same as key return.
- 3) If middle element is lesser than key then
  - ....3a) search submatrix on lower side of middle element
  - ....3b) Search submatrix on right hand side of middle element
- 4) If middle element is greater than key then
  - ....4a) search vertical submatrix on left side of middle element
  - ....4b) search submatrix on right hand side.

        int rowcount = 4,colCount=4,key=50;
        for (int i=0; i<rowcount; i++)
            for (int j=0; j<colCount; j++)
                search(mat, 0, rowcount-1, 0, colCount-1, mat[i][j]);
    }
}

```

```

// A divide and conquer method to search a given key in mat[]
// in rows from fromRow to toRow and columns from fromCol to
// toCol
public static void search(int[][] mat, int fromRow, int toRow,
                          int fromCol, int toCol, int key)
{
    // Find middle and compare with middle
    int i = fromRow + (toRow-fromRow)/2;
    int j = fromCol + (toCol-fromCol)/2;
    if (mat[i][j] == key) // If key is present at middle
        System.out.println("Found " + key + " at " + i +
                           " " + j);
    else
    {
        // right-up quarter of matrix is searched in all cases.
        // Provided it is different from current call
        if (i!=toRow || j!=fromCol)
            search(mat,fromRow,i,j,toCol,key);

        // Special case for iteration with 1*2 matrix
        // mat[i][j] and mat[i][j+1] are only two elements.
        // So just check second element
        if (fromRow == toRow && fromCol + 1 == toCol)
            if (mat[fromRow][toCol] == key)
                System.out.println("Found " + key + " at " +
                                   fromRow + " " + toCol);

        // If middle key is lesser then search lower horizontal
        // matrix and right hand side matrix
        if (mat[i][j] < key)
        {
            // search lower horizontal if such matrix exists
            if (i+1<=toRow)

    }

    // If middle key is greater then search left vertical
    // matrix and right hand side matrix
    else
    {
        // search left vertical if such matrix exists
        if (j-1>=fromCol)
            search(mat, fromRow, toRow, fromCol, j-1, key);
    }
}
}

```

### Time complexity:

We are given a  $n \times n$  matrix, the algorithm can be seen as recurring for 3 matrices of size  $n/2 \times n/2$ . Following is recurrence for time complexity

$$T(n) = 3T(n/2) + O(1)$$

The solution of recurrence is  $O(n^{1.58})$  using [Master Method](#).

But the actual implementation calls for one submatrix of size  $n \times n/2$  or  $n/2 \times n$ , and other submatrix of size  $n/2 \times n/2$ .

In main function why is it there :

```
for (int i=0; i<rowcount; i++)="" for="" (int="" j="0;" j<colcount;="" j++)="" searc  
colcount-1,="" mat[i][j]);="">
```

**kaushik Lele** → Aman • 11 days ago

It is for testing purpose. Every element is searched one by one.

worst case time complexity of the implementation can be written as

$T(m, n) = \text{MAX}(T(m/2, n), T(m, n/2)) + T(m/2, n/2)$

^ | v • Reply • Share ›

**ravi** → ravi • 15 days ago

m is number of rows and n is number of columns in input matrix
